

Value-Based Prioritization⁷

Kevin Grigorenko⁶

January 11, 2019

Abstract

A method is proposed to use value theory to quantitatively prioritize potential actions to accomplish a goal. This method is applied to the example of choosing meaningful work using an example value system based on the desire to reduce suffering.

1 Introduction

Why should a particular goal be pursued (“Why”)? Given a goal, what actions should be pursued to best accomplish said goal (“What”)? Given an action, how should said action be pursued (“How”)?

This article proposes that value theory usually best scopes “Why” and “What” and the scientific method usually best answers “How”. A method called Value-Based Prioritization (1) is developed to answer the “What” question:

Why: *Value Theory*

↓

What: ***Value-Based Prioritization*** (1)

↓

How: *Scientific Method*

2 Why a Goal?

“Why a Goal?” is usually best scoped using a value system because value systems are evaluative by nature¹³. Evaluating different value systems is left as an (lifelong) exercise for the reader*.

*Example value systems include intuitionism⁹, consequentialism¹⁴, evolutionary biology⁵, religion⁸,

3 What Actions?

“What Actions?” is usually best scoped by prioritizing actions because actions usually have differing effect sizes. It follows from the value system used to answer “Why” that the same value system is used primarily to evaluate the priority of each action.

This article proposes a method called Value-Based Prioritization which builds a quantitative prioritization model based on predicted effect sizes. Raw prioritization scores are further scaled by contextual factors such as implementation time, cost, risk, and other judgments.

4 How to do an Action?

Given answers to “Why?” and “What?”, how to implement actions is usually best answered with the scientific method¹: observations are made and rational thought is used to generate hypotheses, hypotheses are tested with experiments, and successful experiments lead to theories and results.

epicureanism¹¹, objectivism², stoicism³, political liberalism¹⁵, communitarianism⁴, anarcho-capitalism¹⁰, etc.

5 Value-Based Prioritization

A **value system** V generates a **goal** $G(t)$ (for some future time t) and a set of **mutually exclusive potential future actions** $A(t) = \{A_1(t), \dots, A_N(t)\}$.

An action's **estimated relative accomplishment amount** $B(A(t))$ (2) is an action's expected *relative* (i.e. with respect to other actions) contribution towards accomplishing $G(t)$:

$$\begin{aligned} B(A(t)) &= \mathbb{R}, \\ 0 &\leq \mathbb{R} \leq 1 \end{aligned} \quad (2)$$

Thus, $G(t)$ is fully accomplished if all actions are accomplished:

$$G(t) = \sum_{i=1}^N B(A_i(t)) = 1 \quad (3)$$

A **value-based prioritization score** $P(A(t))$ (4) is the result of the product of a set of **value-based prioritization scale functions** $S = \{S_1, \dots, S_N\}$ multiplied by (2):

$$\begin{aligned} P(A(t)) &= B(A(t)) \cdot \prod_{j=1}^N S_j(A(t)), \\ 0 &\leq S_j(B(A(t))) \leq 1 \end{aligned} \quad (4)$$

The set S always includes the element $S_0(A(t)) = 1$. Note that $\sum_{i=1}^N P(A_i(t)) \neq G$ if any $S_j(A_i(t)) < 1$. Example scale functions include cost, risk, etc.

A **value-based prioritization** $\beta(t)$ (5) is a sequence of actions ordered by prioritization score (4) in descending order:

$$\begin{aligned} \beta(t) &= (A_1(t), \dots, A_N(t)), \\ P(A_1(t)) &\geq \dots \geq P(A_N(t)) \end{aligned} \quad (5)$$

The first j actions in $\beta(t)$ should be executed in descending priority/proportion where j is chosen based on available concurrency.

6 Modeled Value-Based Prioritization

Historical data may be used to predict actions' estimated relative accomplishment amounts (2).

If an action has historical data $D(t)$ (6):

$$D(t) = ((t_1, D(t_1)), \dots, (t_N, D(t_N))) \quad (6)$$

Then, a set of **comparable prediction models** $R(t) = \{R_1(t), \dots, R_N(t)\}$ (e.g. linear regression) is applied to each $D(t)$. The models are compared and the **best fitting model** $M(t)$ is selected (e.g. using ANOVA).

Next, the model $M(t)$ is used to predict each $A(t_F)$ for some time in the future t_F (e.g. the average time an action will take to ramp up implementation). Note that each $D(t)$ may have a different $M(t)$.

Finally, $B(A(t_F))$ is calculated for all A and value-based prioritization is applied to generate **modeled value-based prioritization** $\beta(t_F)$ (7):

$$\begin{aligned} \beta(t_F) &= (A_1(t_F), \dots, A_N(t_F)), \\ P(A_1(t_F)) &\geq \dots \geq P(A_N(t_F)) \end{aligned} \quad (7)$$
